Alloimmunization comes with a heavy
psychosocial burden for the mother

The Allo Hope Foundation

Who We Are

The Allo Hope Foundation is a U.S.-based nonprofit organization founded and led by alloimmunized patients with backgrounds in education, clinical care, and research. Our mission is to prevent harm, stillbirth, or infant death caused by alloimmunization and Hemolytic Disease of the Fetus and Newborn (HDFN).

Our Medical Advisory Board includes experts in maternal-fetal medicine and neonatal care, collaborating on evidence-based resources, research and the highest level of patient care.

Juan M. González Vélez, MD PhD
Enrico Lopriore, MD
Kara B Markham, MD
Kenneth J Moise Jr., MD

Dick Oepkes, MD
Saul Snowise, MD
Thomas N. Trevett, MD

What We Do

- Daily peer support and education to alloimmunized patients
- Speak, research, and publish on the needs of the alloimmunized community, advocating for optimal, evidence-based treatment
- Promote and contribute to the highest standards of alloimmunized pregnancy and HDFN care

To connect with a Maternal-Fetal Medicine specialist, request educational materials, or arrange peer support for an alloimmunized patient, contact us at info@allohopefoundation.org

Maternal Red Cell Alloimmunization:

Evidence-Based Management
for Optimal HDFN Outcomes

Managing an alloimmunized pregnancy requires
precisely timed diagnosis, monitoring and treatment.

CRITICAL PERIODS AND TIME SENSITIVE CARE IN THE PRENATAL HDFN COURSE

Gestational Age in Weeks													
3-5	6-9	10-12	13-14	15-16	17-18	19-21	22-25	26-27	28-30	31-34	35-36	37-38	39-40
Embryo/Fetus not at risk for hemolytic fetal anemia				Window of risk for fetal anemia									
Dating Ultrasound for Accurate GA													
Maternal Antibody Screen, followed by referral to MFM if positive													
Maternal Antibody Titers. If below critical, check every 4 weeks before 25 weeks.								If below critical, check every 2 weeks after 24 weeks					
Paternal Antigen Test can be performed to help determine fetal antigen status													
				Free fetal DNA test can be performed to determine fetal antigen status									
				Weekly IVIG can be used for patients at risk for severe disease Most effective when started before 13 weeks									
				MCA Doppler Ultrasounds used to monitor for fetal anemia								MCA less accurate after 35 weeks	
				Intrauterine Blood Transfusions can be performed to treat fetal anemia									
KEY								Viability Begins		Weekly NSTs or BPPs			
● Window of Risk for Fetal Anemia													
● Diagnosis and Risk Assessment													
● Fetal Monitoring													
● Treatment													
● Delivery													
● Important Milestones													
										Deliver By 37-38 weeks			

With proactive monitoring and skilled
intervention, expect fetal survival for
the pregnancy complicated by
alloimmunization/HDFN.

How You Can Help

Refer patient to Allo Hope Foundation
for education and social support

Offer referral to mental health
professional as anxiety and
depression are reported in 91%
and 68%, respectively, of
alloimmunized patients

ALLO HOPE FOUNDATION
BILLION TO ONE

Prenatal

Diagnosis and Risk Assessment

If patient has positive RBC antibody screen

- Follow with antibody ID (CPT 86870) and titer (CPT 86905)

If antibody is known to cause HDFN

- Refer to MFM with specific skill in conducting intrauterine transfusions (may be out of state; contact Allo Hope Foundation for a recommended provider)
- Order paternal antigen phenotyping (RhD: 86901; C, c, E, e: 86906; Others: 86905)

If paternal antigen result is heterozygous

- Consider UNITY Fetal Antigen test as early as 10 weeks gestation for patients with D, K, C, c, E or Fya antibodies
- Can consider optional amniocentesis for patients with other antibodies, though this could increase antibody titer. Otherwise monitor as if fetus is antigen positive

If fetus is negative for the antigen in question

- Fetus is not at risk for HDFN, regardless of maternal antibody titer; manage pregnancy normally. No further titer assessments needed

If titers are critical (≥ 4 for Kell, ≥ 16 for other antibodies)

- Do not allow fetal antigen status determination to delay referral to MFM

If titers are below critical

- Monitor titers every month until 24 weeks, then every two weeks thereafter

Fetal Monitoring

Patients at risk for Early-Onset Severe HDFN (titers of ≥ 64 for Kell, ≥ 128 for others, or history of severe HDFN) require prompt, early referral to MFM as their care is extremely time sensitive

If patient has critical titers

- Middle cerebral artery (MCA) Doppler ultrasounds can begin as early as 15 weeks gestation in skilled fetal centers (CPT 76821) and should be initiated no later than 16 weeks gestation

Once MCA Doppler scans have been initiated

- Continue to scan weekly as hemolytic fetal anemia can develop in less than one week

When the patient reaches 32 weeks GA

- Begin weekly BPP or NSTs until delivery regardless of titer

Treatment

If patient is at risk for Early-Onset Severe HDFN (titers of ≥ 64 for Kell, ≥ 128 for others, or history of severe HDFN)

- Patient may benefit from IVIG with or without therapeutic plasma exchange. IVIG has been shown to delay time to first IUT by three weeks or more

An MCA-PSV at or above 1.5 MoM for gestational age

- Indicates possible severe anemia requiring intrauterine blood transfusion (IUT)
- Note that a severely anemic early fetus may not show visible signs of anemia such as hydrops other than an elevated MCA Doppler value
- IUT outcomes decline significantly if fetus is hydropic. Initiate IUT based on MCA Doppler values and do not wait for ascites or hydrops to develop

Be aware of emerging FcRn blockade treatments in clinical development

Delivery

In advance of delivery

- Offer to facilitate NICU tour and pediatric hematology consult for family
- Prepare cross-matched blood for alloimmunized mother and infant at time of delivery

If fetus is known or assumed to be antigen positive

- Deliver by 37-38 weeks GA regardless of antibody titer

Neonatal

After delivery families can expect:

Cord blood drawn at birth

- For Direct Coombs Test (DCT/DAT) to confirm HDFN
- For bilirubin, hematocrit/hemoglobin test

Frequent bilirubin assessment

- Consistent with AAP guidelines

Potential NICU admission

- For prematurity, phototherapy, exchange or top-up transfusion, neonatal IVIG

After discharge families can expect:

In advance of hospital discharge

- Provider assistance in identifying a pediatric hematologist for follow up care

Monitoring for delayed onset anemia

- Weekly Hgb/Hct and retic up to three months of age
- Anemia often doesn't require transfusion until 2 weeks or more after delivery
